Overview and Objectives

Economics 2148 is one of the second-year econometrics field classes. We will begin the class with a survey of the literature on identification using instrumental variables, taking the linear model as a point of departure. The linear model imposes strong restrictions on the heterogeneity of causal effects. Generalizing this model to allow for nonlinear and heterogeneous effects leads to a variety of approaches discussed in the literature, including a re-interpretation of classic estimands as LATE, bounds on objects such as the ATE that are not point identified, conditional moment restrictions, and control function approaches.

The next part of class will cover some of the theoretical foundations of machine learning, including regularization and data-driven choice of tuning parameters. We will discuss in some detail the canonical normal means model. In this model, we will motivate shrinkage estimators in different ways, and will prove the famous result that shrinkage estimators can uniformly dominate conventional estimators. We will then move from nor-
mal means to function estimation using Gaussian process priors. We will show the equivalence of (empirical) Bayes estimation using such priors to penalized least squares regression with penalties corresponding to so-called reproducing kernel Hilbert space norms. This part of 2148 concludes with some applications of Gaussian process priors to experimental design and to optimal taxation.

After the spring break, we will cover some selected additional topics in machine learning. We will begin this part with a discussion of methods developed for use with text data, in particular topics models. We will then introduce regression trees and random forests, which have found some popularity in empirical economics. We will next discuss (deep) neural nets, including some numerical methods used for training them, such as stochastic gradient descent. After that, we will review methods for active learning in the context of multi-armed bandit settings. We will review some theoretical results providing performance guarantees (regret bounds) for algorithms used for learning in bandit settings. We will then turn to a generalization of bandit problems, Markov decision problems, and will discuss reinforcement learning approaches for solving these. Lastly, we will talk a bit about data visualization.

At some point early in the semester, I will provide an introduction to R. R is an open source statistical software with a large and growing community, which (I believe) will increasingly supplant other environments such as Stata and Matlab.

We will conclude the semester with in-class discussions of research proposals by you that are related to the topics covered. We will do so in a fairly informal manner, based on brief presentations by you and subsequent open discussion.

Requirements and policies

Your grade for Economics 2148 will be determined based the following assignments. You are asked to complete two computer-based problem sets, and to submit summaries of two papers of your choice from the references at the end of this Syllabus. I am happy to make recommendations if you are not sure which ones to pick. You will also have to prepare a research proposal, of 3-10 pages, and to give a brief presentation of your proposal in class. Proposals could be applied or theoretical, but are ideally related to some of the topics covered in class. Please upload both your problem set solutions, summaries, and research proposal via Canvas.
These assignments contribute to your grade as follows.

1. Two summaries of about 3 pages length each (10% of grade each).

2. Two problem set solutions (10% of grade each).

3. In-class midterm exam on October 22 (30% of grade).

4. A research proposal and presentation. (30% of grade).

Additionally, the slides contain a lot of “practice problems,” which you will have to solve in class. The idea is to have you complete most of the proofs, after I pointed you in the right direction. After a few minutes, we will discuss the solutions to these problems. These problems provide good guidance for what you might expect from the midterm exam.

I encourage you to come to office hours with any questions. If you need any special accommodations for physical or medical reasons, please see me after class or send me an email.
Outline of the course

Instrumental variables part I – origins and binary treatment

- Origins of instrumental variables: Systems of linear structural equations
- Strong restriction: Constant causal effects.
- Modern perspective: Potential outcomes, allow for heterogeneity of causal effects
- Keep IV estimand, reinterpret it in more general setting: Local Average Treatment Effect (LATE)
- Keep object of interest: Average Treatment Effect (ATE) Partial identification (Bounds)

Instrumental variables part II – continuous treatment

- Restricting heterogeneity in the structural equation: Nonparametric IV (conditional moment equalities)
- Restricting heterogeneity in the first stage: Control functions
- Linear IV: Continuous version of LATE

Review of decision theory

- Basic definitions
- Optimality criteria
- Relationships between optimality criteria
- Analogies to microeconomics
- Two justifications of the Bayesian approach
Shrinkage in the normal means model

- Setup: the normal means model $X \sim N(\theta, I_k)$ and the canonical estimation problem with loss $\|\hat{\theta} - \theta\|^2$.
- The James-Stein (JS) shrinkage estimator.
- Three ways to arrive at the JS estimator (almost):
  1. Reverse regression of $\theta_i$ on $X_i$.
  2. Empirical Bayes: random effects model for $\theta_i$.
  3. Shrinkage factor minimizing Stein’s Unbiased Risk Estimate.
- Proof that JS uniformly dominates $X$ as estimator of $\theta$.
- The normal means model as asymptotic approximation.

Gaussian process priors, reproducing kernel Hilbert spaces, and Splines

- 6 equivalent representations of the posterior mean in the normal-normal model.
- Gaussian process priors for regression functions.
- Reproducing Kernel Hilbert Spaces and splines.

Applications of Gaussian process priors from my own work

- Optimal treatment assignment in experiments.
  - Setting: Treatment assignment given baseline covariates
  - General decision theory result: Non-random rules dominate random rules
  - Prior for expectation of potential outcomes given covariates
  - Expression for MSE of estimator for ATE to minimize by treatment assignment
- Optimal insurance and taxation.
  - Review: Envelope theorem.
  - Economic setting: Co-insurance rate for health insurance.
  - Statistical setting: prior for behavioral average response function.
  - Expression for posterior expected social welfare to maximize by choice of co-insurance rate.
Regression trees and random forests
- Regression trees: Splitting the covariate space.
- Random forests: Many trees.
- Causal forests: Predicting heterogeneous causal effects.

Text analysis
- Representing text as data.
- Text regression.
- Generative language models.
- Hierarchical Dirichlet processes.

Deep neural nets
- What are neural nets?
- Network design:
  Activation functions, network architecture, output layers.
- Calculating gradients for optimization:
  Backpropagation, stochastic gradient descent.
- Regularization using early stopping.

Bandit problems
- Setup: The multi-armed bandit problem.
  Adaptive experiment with exploration / exploitation trade-off.
- Two popular approximate algorithms:
  1. Thompson sampling
  2. Upper Confidence Bound algorithm
- Characterizing regret.
- Characterizing an exact solution: Gittins Index.
- Extension to settings with covariates (contextual bandits).
Reinforcement learning

- Markov decision problems.
- Expected updates – dynamic programming.
- Sample updates:
  - On policy: Sarsa.
  - Off policy: Q-learning.
- Approximation:
  - Off policy: Semi-gradient Q-learning.
  - Deep reinforcement learning.

Data visualization

- The “layered grammar of graphics:” A framework for describing mappings from data to visual representations.
- ggplot2, a popular graphics package for R.
- Good design practices for visualization:
  1. Show the data.
  2. Reduce the clutter.
  3. Integrate the text and the graph.
